5. Visualization and troubleshooting with VMD

# 1

## Basic input

## User input for Targeted MD

```
colvar {  
    name RMSD  
  
    rmsd {  
        atoms {  
            atomsFile beta.pdb  
            atomsCol 0  
        }  
        refPositionsFile beta.pdb  
    }  
}  
  
harmonic {  
    colvars RMSD  
  
    centers 5.3  
    targetCenters 0.0  
    targetNumSteps 200000  
    forceConstant 100.  
}
```

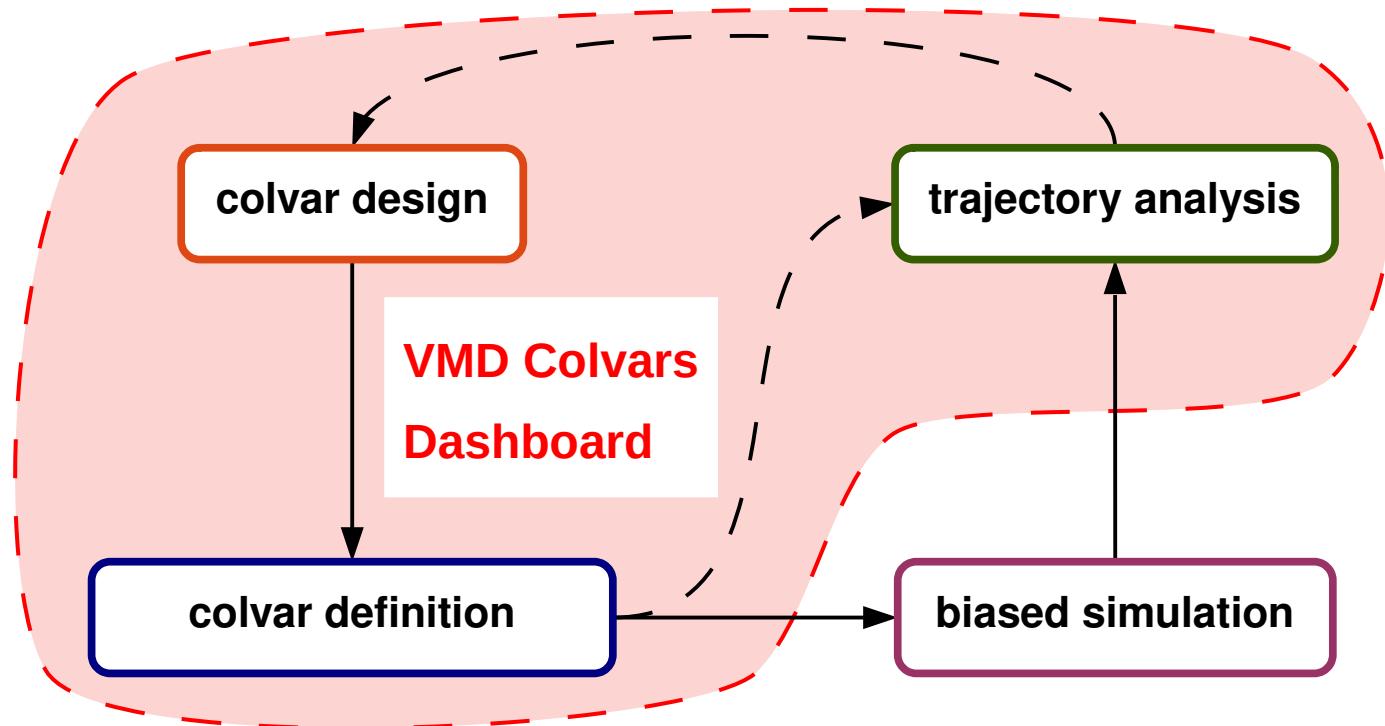

Colvars + NAMD simulation

# 3

## Simulation with NAMD

## Running a Colvars/NAMD simulation

- activate Colvars in NAMD's config file:

```
colvars      on
colvarsConfig my_cfg.colvars
colvarsInput  previous_run.colvars.state # Restart
```

- run NAMD:

```
namd3 +p8 mysim.namd > mysim.log &
```

# Reading the Colvars output

```
colvars: Initializing the collective variables module, version 2024-06-04.          library version
colvars: Please cite Fiorin et al, Mol Phys 2013:
colvars:   https://doi.org/10.1080/00268976.2013.813594
colvars: as well as all other papers listed below for individual features used.
colvars: This version was built with the C++11 standard or higher.
colvars: Summary of compile-time features available in this build:
colvars:   - SMP parallelism: enabled (num. threads = 8)
colvars:   - Lepton custom functions: available
colvars:   - Tcl interpreter: available
colvars: Redefining the Tcl "cv" command to the new script interface.
colvars: Using NAMD interface, version "2023-12-05".
```

features

# Colvars Module under the hood

## Performance issues

- performance bottlenecks:
  - computation
  - communication
- Colvars always runs on the CPU
  - takes advantage of multi-core CPUs (smp option)
- NAMD3 can run GPU-resident
  - requires data transfers from GPU to main memory
  - faster simulations → more probable that colvar calculation is a bottleneck

## Performance tuning

- most computationally expensive colvar: coordNum ( $n \times m$ )
  - can be improved with pair lists
- communication-intensive colvars:
  - anything with many atoms!
- solutions:
  - tune the performance of NAMD first (GPU-resident, etc.)
  - use as few atoms as possible for colvars
  - enable smp, reserve several cores
  - for slow colvars, enable timeStepFactor (MTS)

# 4

## Making the most of scripts

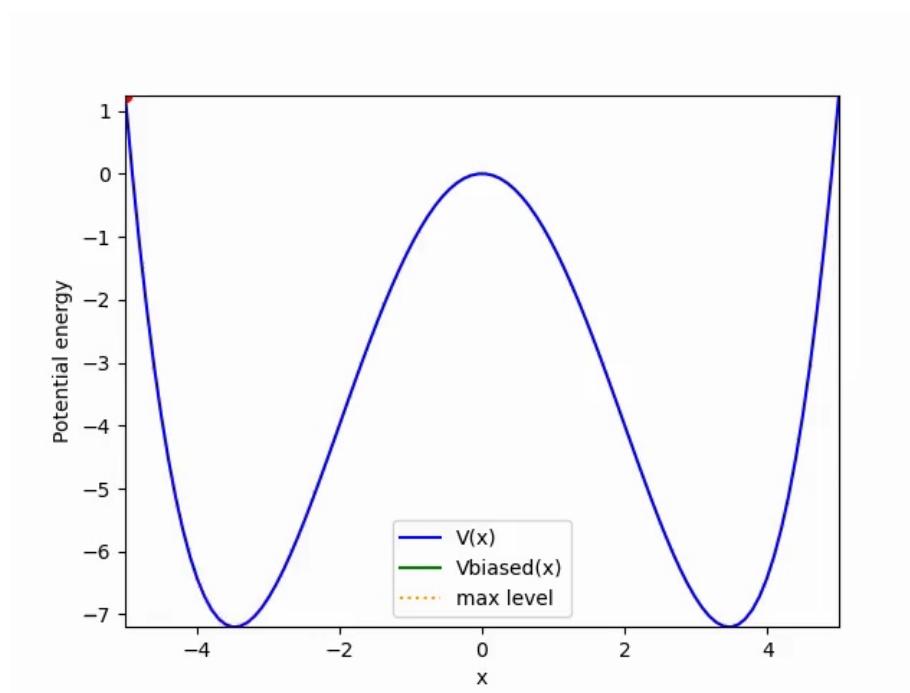

## User-facing flexibility

- new variables can be created **at run-time** as combinations of basis functions:
  - polynomial
  - symbolic expressions (Lepton)
  - Tcl scripts
- new biasing algorithms can be written as Tcl scripts
- the NAMD config file is a Tcl script

# Adiabatic Bias MD: selecting forward fluctuations

M. Marchi & P. Ballone JCP 1999

- one-sided **harmonic restraint** with constant  **$k$**
- **ratchet** mechanism: restraint follows maximum level

# ABMD: a quick implementation

Colvars / Tcl script:

```
proc calc_colvar_forces {ts} {
    set z [cv colvar z value]
    if {$z > $max} {                                ;# above high-water mark?
        if {$z <= $target} {set max $z}            ;# raise it until target
    } else {
        cv colvar z addforce [expr $k * ($max - $z)] ;# else apply bias
    }
}                                                 ;# that's it
```

In Colvars config:

```
scriptedColvarForces on
colvar {
    name z
    ...
}
```

# Scripting NAMD with Colvars

```
set terminate false

while { ! $terminate } {
    set cv_value [cv colvar $myCV value]
    cv config [new_cfg $cv_value]      ;# change Colvars config
    if [criterion $cv_value] {
        set terminate true          ;# terminate depending on CV
    }
    run $nSteps                      ;# advance simulation
}
```

# 5

## Visualization and troubleshooting with VMD

# Demo

- visualize
  - atoms
  - forces
- check PBCs
  - broken up atom groups?
- compare colvar trajectories
